Landslides (Mass Wasting)

KING'S  
College  
LONDON

# *Table of Contents*

---

- 1. Landslides Introduction**
- 2. Types of Mass Wasting Processes**
- 3. Factors Influencing Slope Stability**
- 4. Triggered Landslide Events**
- 5. Triggering Events and Road Networks**
- 6. Hazard Assessment of Mass Wasting**
- 7. Prevention and Mitigation of Mass Wasting**
- 8. Further Resources**

# 1. Landslides Introduction

---

- **Mass-Wasting:** down slope movement of rock and **regolith** near Earth's surface, mainly due to force of gravity.
- **Regolith:** unconsolidated rock debris, including the basal soil horizons, overlying bedrock.
- The down-slope movement of material, whether bedrock, regolith, or a mixture, is commonly referred to as a **landslide**.

# 1. Landslides Introduction

---

- **Mass-wasting important part of *erosional process*.**
  - *Moves material from higher to lower elevations.*
  - *Streams and glaciers can then pick up material.*
- **Mass-wasting occurs *all the time* on *all* slopes.**
- **Sometimes slow, sometimes very sudden.**
- **As human populations expand and occupy more and more of the land surface, *mass-wasting processes become more likely to affect humans*.**

# 1. Landslides Introduction

<i>Year</i>	<i>Location</i>	<i>Type</i>	<i>Fatalities</i>
1916	Italy, Austria	Landslide	10,000
1920	China	Earthquake triggered landslide	200,000
1945	Japan	Flood triggered landslide	1,200
1949	USSR	Earthquake triggered landslide	12,000–20,000
1954	Austria	Landslide	200
1962	Peru	Landslide	4,000–5,000
1963	Italy	Landslide	2,000
1970	Peru	Earthquake related debris avalanche	70,000
1985	Columbia	Mudflow related to volcanic eruption	23,000
1987	Ecuador	Earthquake related landslide	1,000

# 1. Landslides Introduction

---

- **Typical year in USA:** landslides cause >\$1.5 thousand million in damages, 25–50 deaths.
- **In other countries**, especially less developed, the loss is usually higher because of:
  - (1) higher population densities
  - (2) lack of zoning laws
  - (3) lack of information about mass-wasting hazards
  - (4) lack of emergency preparedness
- **Knowledge about relationships between local geology and mass-wasting processes can lead to better planning that can reduce vulnerability to such hazards.**

**Lots of classifications.**

**Cover 'rapidly' here without lots of detail.**

**Photos/videos excellent for high-school classes.**

**See 'notes' on each slide for links and details.**

## 2. Types of Mass-Wasting Processes

- Processes generally grade into one another, so classification is somewhat difficult.
- Two broad categories, but many different classification schemes exist:
  - 2.1 Slope Failures:** sudden failure of the slope resulting in transport of debris down hill by sliding, rolling, falling, or slumping.
  - 2.2 Sediment Flows:** debris flows down hill mixed with water or air.

**Video showing deep-seated San Mateo slump.**

- Occurred in San Mateo County (California), USA, a few days after a 1997 New Year's storm.
- Slump opened a large fissure on the uphill scarp and created a bulge at the downhill toe.
- Movement continued at average rate of a meter per day.
- Uphill side dropped further, broke through a retaining wall, and created a deep depression.
- At the same time the toe slipped out across the road.
- Over 250,000 tons of rock and soil moved in this landslide.

## 2. *Types of Mass-Wasting Processes*

---

- Processes generally grade into one another, so classification is somewhat difficult.
- Two broad categories, but many different classification schemes exist:
  - 2.1 Slope Failures:* sudden failure of the slope resulting in transport of debris down hill by sliding, rolling, falling, or slumping.
  - 2.2 Sediment Flows:** debris flows down hill mixed with water or air.

# 2. Types of Mass-Wasting Processes

## 2.2 Sediment Flows

- **Sediment flows** occur when sufficient force is applied to rocks and regolith, so they begin to flow down slope.
- A sediment flow is a mixture of rock and/or regolith with some water or air.
- **Sediment flow types** (*depends on % water present*):

### 2.2.1 Slurry Flows: 20–40% water present.

As water content increases above 40% slurry flows grade into streams.  
Slurry flows are considered water-saturated flows.

### 2.2.2 Granular Flows: 0–20% water present.

Granular flows are possible with little or no water.  
Fluid-like behaviour is given these flows by mixing with air.  
Granular flows are not saturated with water.

# 2. Types of Mass-Wasting Processes

## 2.2 Sediment Flows

- Sediment flows can be further subdivided on the basis of the **velocity at which flow occurs.**

# 2. *Types of Mass-Wasting Processes*

## 2.2 *Sediment Flows*

8. Further Resources

[walrus.wr.usgs.gov/infobank](http://walrus.wr.usgs.gov/infobank)

# 3. Factors Influencing Slope Stability

## 3.1 Gravity

- **Gravity:** Main force responsible for mass wasting.
- On flat surface force of **gravity acts downward**.
- So long as the material remains on the flat surface it will not move under the force of gravity.

# 3. Factors Influencing Slope Stability

## 3.1 Gravity

- **Perpendicular component ( $g_p$ ):** helps to hold the object in place on the slope.
- **Tangential component ( $g_t$ ):** causes a *shear stress* parallel to the slope that pulls the object in the down-slope direction.

# 3. Factors Influencing Slope Stability

## 3.1 Gravity

- **Shear strength**: All forces resisting movement down the slope including:
  - frictional resistance
  - cohesion among particles making up the object
- When **shear stress** > **shear strength**, the object will move down-slope.
- **Shear stress** is INCREASED by
  - steeper slope angles.
- **Shear strength** is DECREASED by:
  - lowering cohesion among the particles
  - lowering the frictional resistance.

8. Further Resources

# 3. *Factors Influencing Slope Stability*

## 3.2 *Water*

---

- ***Water*** not always directly involved as transport in mass-wasting processes, but plays important role.

# 3. Factors Influencing Slope Stability

## 3.2 Water

- Imagine a **SAND CASTLE**.
- ***Sand totally dry***: impossible to build a pile of sand with a steep face like a castle wall.
  - ***If sand a little wet***: can build vertical wall.
  - ***If sand too wet***: flows like a fluid and cannot remain in position as a wall.

# 3. Factors Influencing Slope Stability

## 3.2 Water

- **Angle of repose for DRY material:** usually lies between about  $30\text{--}37^\circ$  [increases with increasing grain size].

# 3. Factors Influencing Slope Stability

## 3.2 Water

- **Angle of repose for SLIGHTLY WET unconsolidated materials: very high angle of repose [because surface tension between water & solid grains tends to hold the grains in place].**

# 3. Factors Influencing Slope Stability

## 3.2 Water

- **Angle of repose for material SATURATED WITH WATER: very small values** [material tends to flow like a fluid].

## NATURAL HAZARD DEMONSTRATIONS FOR TEACHING

2005 AGU Session ED13C: Lecture Demonstrations in Earth Science Curriculum  
Poster ED13C-1159

**Bruce D. Malamud**  
Hazards, Vulnerability & Risk Research Unit  
Department of Geography  
King's College London, UK  
e-mail: bruce.malamud@kcl.ac.uk

### I. Summary

This paper presents several demonstrations for large classes that have been developed or gathered from other sources in the general area of natural hazards. These include weather (Figures A, B, F), earthquakes (Figures C, D), mass movements (Figures E, G), tsunamis (Figure H), and volcanoes (Figures I).

### II. Teaching Large Classes

There are many methods of teaching, but as university lecturers, particularly for large class sizes, we find ourselves too often presenting material to students by direct speaking, or some combination of blackboard, whiteboard, slide projector, digital projector, and overheads.

### III. Actively Involving Students?

There are many techniques in large classes to more actively involve students, so that teaching is not just 'receiving of information', including (a) breaking up students into small group discussions during lectures, (b) encouraging students to actively participate in class through comments, questions and 'show of hands', (c) group 'role playing' exercises, (d) **hands-on activities**, (e) **class demonstrations**.

This paper concentrates on the last two, specifically for natural hazards.

### IV. Class Demonstrations

As a teaching tool, students often become much interested and more excited about what they are learning if use is made of 5–10 minute **demonstrations**, even if only peripherally related to the subject at hand.

Resultant discussion with questions and comments by students keeps both the students and the lecturer (in this case the author) motivated and intrigued about the subjects being discussed.

Days, weeks, and months later, the students remember these 'demonstrations', but to set these up takes time, effort, and resources of equipment, although not necessarily a large amount of the latter.

Several natural hazards demonstrations are presented here, most inexpensive, that have been used in front of large university classes and smaller 'break-out groups', and which can also be adapted for secondary-school students. Many other demonstrations exist (see **V. Bibliography**).

### A. Tornado Tube 'Vortex'

No water! The vacuum from the bottle is the cause of the vortex in the water. (Tornado Tube) (Tornado Tube) in the UK.

Gentle circular twist of bottle causes vortex. Tornado Tubes are inexpensive and available from many science centers and 'educational shops'. See Sanger (2005) and other references under 'Weather' part V.

### B. Tame Tornado

Called 'Tame Tornado' (from 'Tornado' in the USA and 'Tame Tornado' (Tame Tornado) in the UK). Add a little water, swirl of opposite very high. Add more water, sediment saturated (bottom fall) and start of vortex very low, sediment rises like a float in vortex and is saturated in front of bottle, sediment rises still high.

### C. Earthquake Waves and Slinky

See Briles (2005) under 'Earthquake' Part V for an extensive teacher's guide on using the slinky to demonstrate seismic waves.

### E. Mass Movement

Dry sand in bottle - 1/2 - 2/3 full. Add a little water, swirl of opposite very high. Add more water, sediment saturated (bottom fall) and start of vortex very low, sediment rises like a float in vortex and is saturated in front of bottle, sediment rises still high.

### F. Air Pressure

There are many demonstrations for 'weather' phenomena (mass gases, tornadoes, wind, air pressure in general, etc.) see references under 'Weather' in Part V.

### G. Mass Movement

Water and sediment swirl in bottle. Subaqueous landslide.

### I. Volcanoes

'Lava Lamp' (from 'Volcano World' (2005)). See Barker (2005) and Volcano World (2005) under 'Volcano' in Part V, for many volcano demonstrations.

### D. Earthquake Stick-Slip

See Briles (2005) under 'Earthquake' Part V for an in-depth discussion of an earthquake demonstration involving stick-slip.

### V. Bibliography and References Cited

### VI. Do you have natural hazard demonstration ideas and references? Please send them to me!

I am compiling a bibliography of resources on natural hazard demonstrations and 'quick' hands-on activities that can be used for university lectures, including web pages, books, science museum literature, journal articles, 'private' ideas (which will be properly acknowledged), items to buy off the shelf, etc. I would be grateful if you could send me any resources you know of, to [bruce.malamud@kcl.ac.uk](mailto:bruce.malamud@kcl.ac.uk).

**Acknowledgements:** Funding for materials used in and published for these demonstrations, see Briles, D. (2005) Earthquakes: A teacher's guide for teachers. (2nd ed.) Available online at: [www.kcl.ac.uk/~geog/briles/earthquakes.html](http://www.kcl.ac.uk/~geog/briles/earthquakes.html) (Accessed 21 Nov 2012).

### H. Tsunami Wave Tank

There are not always easy to make so that they are 'teachable' and demonstrations are listed under 'Tsunami' in Part V.

# 4. Triggered Landslide Events

## 4.1 Major Triggers

---

- A mass-wasting event **can occur any time slope becomes unstable.**
- Sometimes, as in **creep**, slope is unstable at all times and process is continuous.
- But other times, **triggers** can occur that cause a sudden instability to occur.

# 4. Triggered Landslide Events

## 4.1 Major Triggers

### EXAMPLES OF MAJOR TRIGGERS

- *Earthquakes* (major shock)
- *Heavy rainfall, Sudden Snowmelt*
  - changes in hydrologic conditions
  - reduce grain to grain contact, reducing angle of repose
  - saturate rock increasing its weight
- *Volcanic Eruptions*
  - shock like explosions
  - earthquakes
  - melting of snow
  - crater lakes empty

# 4. Triggered Landslide Events

## 4.1 Major Triggers

### **LANDSLIDES IN TRIGGERED EVENTS**

**Number:** *After a trigger, might be zero, one or many thousands of landslides that occur.*

**Time:** *Landslides occur in the minutes to weeks after the trigger occurs.*

**Areas:** *Landslide areas range over many orders of magnitude, from  $m^2$  to  $km^2$ .*

# Table of Contents

7. Prevention and Mitigation of Mass Wasting
8. Further Resources

# 4. Triggered Landslide Events

## 4.2 Other Triggers of Landslides

### ➤ OTHER EXAMPLES OF LANDSLIDE TRIGGERS:

#### (i) **SLOPE MODIFICATION.**

- By humans or by *natural causes*.
- Changes *slope angle* so no longer at angle of repose.
- A mass-wasting event can restore slope to its angle of repose.

# 4. Triggered Landslide Events

## 4.2 Other Triggers of Landslides

- **OTHER EXAMPLES OF LANDSLIDE TRIGGERS:**
- (ii) **UNDERCUTTING**

# 4. Triggered Landslide Events

## 4.2 Other Triggers of Landslides

- **OTHER EXAMPLES OF LANDSLIDE TRIGGERS:**
- (iii) **FIRE** can cause *removal of vegetation*, resulting in the regolith becoming less fixed over time.
- (iv) **ADDED MASS** can make a region more prone to mass wasting.

### Examples

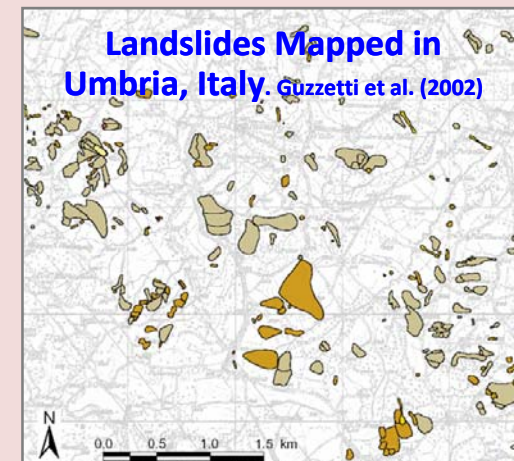

- waste material
- mining tailings
- structures
- water leakage

# 7. Prevention & Mitigation of Mass Wasting

## ➤ *Slope Assessment:*

- *All slopes are susceptible to mass-wasting hazards if a triggering event occurs.*
- *Thus, all slopes should be assessed for potential mass-wasting hazards.*

## ➤ Mass-wasting events can sometimes be avoided by employing *engineering techniques* to make slope more stable.

## ➤ *Engineering mitigation technique examples:*

- (i) Steep slopes can be covered or sprayed with *SHOTCRETE, CONCRETE, or METAL MESH.*
- (ii) *RETAINING WALLS* can be built to stabilize slope.

# 7. Prevention & Mitigation of Mass Wasting

# 7. Prevention & Mitigation of Mass Wasting

## ➤ Engineering mitigation technique examples

# 7. Prevention & Mitigation of Mass Wasting

- **Engineering mitigation technique examples:**
  - (iii) **DEBRIS CHUTES** can be used to channel flows.

(debris torrent chute in Alps)

# 7. Prevention & Mitigation of Mass Wasting

- **Engineering mitigation technique examples:**
  - (iv) **ROCKFALL SHEDS** can protect road/railway.

# 7. Prevention & Mitigation of Mass Wasting

- **Engineering mitigation technique examples:**
- (v) **Drainage pipes** inserted in slope to more easily allow water to get out [thus avoiding fluid pressure increase, liquefaction possibility, or increased weight due to water addition].

# 7. Prevention & Mitigation of Mass Wasting

## ➤ **Engineering mitigation technique examples:**

(vi) **Over-steepened slopes could be graded** to reduce the slope to the natural angle of repose.

## ➤ **Other mitigation technique examples:**

(i) In mountain valleys subject to mudflows, plans could be made to **rapidly lower levels of water in human-made reservoirs** to catch and trap the mudflows.

(ii) **Land use planning:** humans should avoid high risk areas (*what might be problem with implementation of this?*).

# 7. Prevention & Mitigation of Mass Wasting

### Q01. What are landslides?

Click to collapse

A01. A landslide is defined by [Cruden \(1991\)](#) for the Working Party on World Landslide Inventory as a movement of a mass of rock, earth or debris down a slope. Landslides are a type of "mass wasting" which denotes any down slope movement of soil and rock under the direct influence of gravity. The term "landslide" encompasses events such as rock falls, topples, slides, spreads, and flows. The size of individual landslides range from metres squared to kilometres squared (about the size of sixty cricket fields!) The speed they travel at ranges from slow (millimetres per year) to very fast (e.g., as fast as 80 kilometres per hour for debris flows).

An active landslide in the Gansu Province of China (Credit: Bruce D Malamud, 2012). A video of this landslide can be found at [Vimeo](#).

[\[VIDEO\] A large rock fall occurred on 21 January 2014 in the village of Termeno \(Tramin\), South Tyrol, I](#)

The rock fall detached from a rock cliff at about 700 m elevation, and travelled at high speed about one downslope. A very large boulder destroyed a barn, and a second – even larger boulder – stopped near Other boulders stopped at various heights along the landslide path. The rock fall caused the evacuation family. The extraordinary video was taken by a drone.
